

## DESCRIPTION

The MP2661 is a highly integrated, single-cell, Li-Ion/Li-Polymer battery charger with system power path management for space-limited, portable applications. The MP2661 uses input power from either an AC adapter or a USB port to supply the system load and charge the battery independently. The charger features trickle charge, constant current (CC) and constant voltage (CV) regulation, charge termination, and charge status.

The power path management function ensures continuous power to the system by automatically selecting the input, the battery, or both to power the system. This power stage features a low dropout regulator from the input to the system and a 100mΩ switch from the battery to the system. Power path management separates the charging current from the system load, which allows for proper charge termination and keeps the battery in full-charge mode.

The MP2661 provides system short-circuit protection (SCP) by limiting the current from the input to the system and the battery to the system. This feature is especially critical to prevent the Li-Ion battery from being damaged by excessively high currents. An on-chip battery under-voltage lockout (UVLO) cuts off the path between the battery and the system if the battery voltage drops below the programmable battery UVLO threshold, which prevents the Li-Ion battery from being over-discharged. An integrated I<sup>2</sup>C control interface allows the MP2661 to program the charging parameters, such as input current limit, input voltage regulation limit, charging current, battery regulation voltage, safety timer, and battery UVLO.

The MP2661 is available in a 9-pin 1.55mmx1.55mm WCSP package.

## FEATURES

- Fully Autonomous Charger for Single-Cell Li-Ion/Li-Polymer Batteries
- Complete Power Path Management for Simultaneously Powering the System and Charging the Battery
- ±0.5% Charging Voltage Accuracy
- 12V Maximum Voltage for the Input Source
- I<sup>2</sup>C Interface for Setting Charging Parameters and Status Reporting
- Fully Integrated Power Switches and No External Blocking Diode Required
- Built-In Robust Charging Protection Including Battery Temperature Monitoring and Programmable Timer
- PCB Over-Temperature Protection (OTP)
- System Reset Function
- Built-In Battery Disconnection Function
- Thermal Limiting Regulation On-Chip
- Available in a WCSP-9 (1.55mmx1.55mm) Package

## APPLICATIONS

- Wearable Devices
- Smart Handheld Devices
- Fitness Accessories
- Smart Watches

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are registered trademarks of Monolithic Power Systems, Inc.

## TYPICAL APPLICATION

Table 1: Operation Mode Table

Items	I <sup>2</sup> C Control			INT Pin	
	HZ = 1	CEB = 1	FET_DIS = 1	H to L for 16s	H to L for 4s
LDO FET	Off	x	x	x	x
Battery FET (charging)	x	Off	Off	Off for 4s, then on	On
Battery FET (discharging)	x	x	Off	Off for 4s, then on	On

x = no effect

## ORDERING INFORMATION

Part Number*	Package	Top Marking
MP2661GC-xxxx**	WLCSP-9 (1.55mmx1.55mm)	See Below

\* For Tape & Reel, add suffix -Z (e.g. MP2661GC-xxxx-Z)

\*\* "xxxx" is the register setting option. The factory default is "0000." This content can be viewed in the I<sup>2</sup>C register map. Please contact an MPS FAE to obtain a "xxxx" value.

## TOP MARKING

**EZY**

**LLL**

EZ: Product code of MP2661GC

Y: Year code

LLL: Lot number

## PACKAGE REFERENCE

## ABSOLUTE MAXIMUM RATINGS <sup>(1)</sup>

V <sub>IN</sub> .....	-0.3V to +13V
All other pins to GND .....	-0.3V to +6.0V
Continuous power dissipation (T <sub>A</sub> = +25°C) <sup>(2)</sup>	1.1W
Junction temperature .....	150°C
Lead temperature (solder) .....	260°C
Storage temperature .....	-65°C to +150°C

## Recommended Operating Conditions <sup>(3)</sup>

Supply Voltage (V <sub>IN</sub> ) .....	4.35V to 5.5V (USB Input)
I <sub>IN</sub> .....	Up to 455mA
I <sub>SYS</sub> .....	Up to 3A <sup>(5)</sup>
I <sub>CHG</sub> .....	Up to 455mA
V <sub>BATT</sub> .....	Up to 4.545V
Operating junction temp. (T <sub>J</sub> ) ...	-40°C to +125°C

## Thermal Resistance <sup>(4)</sup>

	θ <sub>JA</sub>	θ <sub>JC</sub>
WLCSP-9 (1.55mmx1.55m) ....	114...	12 ... °C/W

### NOTES:

- 1) Exceeding these ratings may damage the device.
- 2) The maximum allowable power dissipation is a function of the maximum junction temperature T<sub>J</sub> (MAX), the junction-to-ambient thermal resistance θ<sub>JA</sub>, and the ambient temperature T<sub>A</sub>. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P<sub>D</sub> (MAX) = (T<sub>J</sub> (MAX)-T<sub>A</sub>)/θ<sub>JA</sub>. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 3) The device is not guaranteed to function outside of its operating conditions.
- 4) Measured on JESD51-7, 4-layer PCB.
- 5) Guaranteed by design

## ELECTRICAL CHARACTERISTICS

V<sub>IN</sub> = 5.0V, V<sub>BATT</sub> = 3.5V, T<sub>A</sub> = +25°C, unless otherwise noted.

Parameter	Symbol	Condition	Min	Typ	Max	Units
Input Source and Battery Protection						
Input voltage range	V <sub>IN</sub>				13	V
Input operation voltage	V <sub>IN</sub>		4.35	5	5.5	V
BATT input voltage <sup>(5)</sup>	V <sub>BATT</sub>				4.5	V
Input over-voltage protection (OVP) threshold	V <sub>IN_OVP</sub>	Input rising threshold	5.85	6	6.15	V
Input OVP hysteresis				350		mV
Input under-voltage threshold	V <sub>UV_IN</sub>	Input rising threshold	3.8	3.9	4.0	V
Input under-voltage threshold hysteresis				170		mV
Input vs. battery threshold	V <sub>IN_BATT</sub>	Input rising vs. battery	100	130	160	mV
Input vs. battery threshold hysteresis				85		mV
BATT under-voltage threshold	V <sub>UV_BATT</sub>	BATT voltage falling, programmable, Reg01 [2:0] = 100 – 2.8V	2.6	2.8	3.0	V
Battery UVLO Range		Programmable using I <sup>2</sup> C	2.4		3.1	V
BATT under-voltage threshold hysteresis				210		mV
Battery over-voltage protection	V <sub>BATT_OVP</sub>	Rising, higher than V <sub>BATT_REG</sub>		130		mV
		Falling, higher than V <sub>BATT_REG</sub>		70		
Power Path Management						
Regulated system output voltage	V <sub>SYS_REG</sub>	V <sub>IN</sub> = 5.5V, I <sub>SYS</sub> = 10mA, I <sub>CHG</sub> = 0A	4.55	4.65	4.75	V

## PIN FUNCTIONS

Package Pin #	Name	I/O	Description
A1	IN	Power	<b>Input power.</b> Place a ceramic capacitor ( $\geq 1\mu\text{F}$ ) from IN to GND as close to the IC as possible.
A2	SYS	Power	<b>System power supply.</b> Place a ceramic capacitor ( $\geq 2.2\mu\text{F}$ ) from SYS to GND as close to the IC as possible.
A3	BATT	Power	<b>Battery.</b> Place a ceramic capacitor ( $\geq 2.2\mu\text{F}$ ) from BATT to GND as close to the IC as possible.
B1	NTC	I	<b>Temperature sense input.</b> Connect a negative temperature coefficient thermistor to NTC. Program the hot and cold temperature window with a resistor divider from VDD to NTC to GND. The charge is suspended when NTC is out of range.
B2	INT	O	<b>Open drain interrupt output.</b> INT can send the charging status and fault interruption to the host. INT is also used to disconnect the system from the battery. Pull INT from high to low for $>16\text{s}$ . The battery MOSFET is off and turns on automatically after $>4\text{s}$ , regardless of the INT state.
B3	VDD	I	<b>Internal control power supply.</b> Connect a ceramic capacitor ( $0.1\mu\text{F}$ ) from VDD to GND. No external load is allowed.
C1	SDA	I/O	<b>I<sup>2</sup>C interface data.</b> Connect SDA to the logic rail through a $10\text{k}\Omega$ resistor.
C2	SCL	I/O	<b>I<sup>2</sup>C interface clock.</b> Connect SCL to the logic rail through a $10\text{k}\Omega$ resistor.
C3	GND	Power	<b>Ground.</b>

## OPERATION

### Introduction

The MP2661 is an I<sup>2</sup>C-controlled, single-cell, Li-Ion or Li-Polymer battery charger with complete power path management. The full charge function features trickle charge (TC), constant current (CC) and constant voltage (CV) regulation, charge termination, auto-recharge, and a built-in timer. The power path function allows the input source to power the system and charge the battery simultaneously. If there is conflict in meeting both the system load and battery charging current, the IC reduces the charging current automatically or uses the battery as a supplemental power to satisfy the system load.

The IC integrates a 300mΩ LDO MOSFET between IN and SYS, and a 100mΩ battery MOSFET between SYS and BATT.

In charging mode, the on-chip 100mΩ battery MOSFET works as a full-featured linear charger with trickle charging, constant current and constant voltage charging, charge termination, auto-recharging, NTC monitoring, built-in timer control, and thermal protection. The charge current can be programmed via the I<sup>2</sup>C interface. The IC limits the charge current when the die temperature exceeds the thermal regulation threshold (120°C default).

In supplement mode, the 100mΩ battery MOSFET is fully turned on to connect the battery to the system load when the input power is not enough to power the system load. When the input is removed, the 100mΩ battery MOSFET is also fully turned on, allowing the battery to power up the system.

When the system load is satisfied, the remaining current is used to charge the smart power path management battery. The IC reduces the charging current or uses power from the battery to satisfy the system load when its demand is over the input power capacity.

Figure 1 shows the power path management structure of the MP2661.

**Figure 1: Power Path Management Structure**

### Power Supply

The internal bias circuit of the IC is powered from the higher voltage of IN or BATT. When IN or BATT rises above the respective under-voltage lockout (UVLO) threshold, the sleep comparator, battery depletion comparator, and the battery MOSFET driver are active. The I<sup>2</sup>C interface is ready for communication and all registers are reset to the default value. The host can access all registers.

### Input OVP and UVLO

The MP2661 has an input over-voltage protection (OVP) threshold and input UVLO threshold. Once the input voltage exits the normal input voltage range, the Q1 MOSFET is turned off immediately.

When the input voltage is identified as a good source, a 200μs immunity timer is active. If the input power is still sufficient until the 200μs timer expires, the system starts up. Otherwise, Q1 remains off.

Figure 2 depicts the operation profile.

**Figure 2: Input Power Detection Operation Profile**

Figure 3: Battery Charge Profile

### Power Path Management

The IC employs a direct power path structure with the battery MOSFET decoupling the system from the battery, which allows for separate control between the system and the battery. The system is given the priority to start up even with a deeply discharged or missed battery. When the input power is available, even with a depleted battery, the system voltage is always regulated to  $V_{SYS\_REG}$  by the integrated LDO MOSFET.

As shown in Figure 1, the direct power structure is composed of a front-end LDO MOSFET between IN and SYS and a battery FET between SYS and BATT.

The input LDO (using an LDO MOSFET) provides power to the system, which drives the system load directly and charges the battery through the battery FET.

For the system voltage control, when the input voltage is higher than  $V_{SYS\_REG}$ , the system voltage is regulated to  $V_{SYS\_REG}$ . When the input voltage is lower than  $V_{SYS\_REG}$ , the LDO MOSFET is fully on with the input current limit.

### Battery Charge Profile

The IC provides three main charging phases: trickle charge, constant current charge, and constant voltage charge (see Figure 3).

1. *Phase 1 (trickle current charge):* The IC is able to safely trickle charge the deeply depleted battery until the battery voltage reaches the trickle charge to the fast charge threshold ( $V_{BATT\_LOW}$ ). The trickle charge current is programmable via Reg03 bit [1:0]. If  $V_{BATT\_LOW}$  is not reached before the pre-charge timer (1hr) expires, the charge cycle is ceased, and a corresponding timeout fault signal is asserted.
2. *Phase 2 (constant current charge):* When the battery voltage exceeds  $V_{BATT\_LOW}$ , the IC enters a constant-current charge (fast charge) phase. The fast charge current can be programmable via Reg02 bit [4:0].
3. *Phase 3 (constant voltage charge):* When the battery voltage rises to the pre-programmable charge full voltage ( $V_{BATT\_REG}$ ) set via Reg04 bit [7:2], the charge mode changes from CC mode to CV mode, and the charge current begins to taper off.

Assuming the termination function (EN\_BF) is set via Reg05[6] = 1, the charge cycle is considered complete when the following conditions are valid:

- The charge current ( $I_{BATT}$ ) reaches the end of charge (EOC) current threshold ( $I_{BF}$ ), and the 2.5ms delay timer is initiated.
- During the 2.5ms delay period,  $I_{BATT}$  is always smaller than  $I_{BF} + I_{BF\_HYSTERESIS}$ .

The charge status is marked as complete once the 2.5ms delay timer expires.

The charge current is terminated at the same time if TERM\_TMR is set via Reg05 [0] = 0; otherwise, the charge current keeps tapering off.

If EN\_BF = 0, the termination function is disabled, the above actions will not occur. During the charging process, the actual charge current may be less than the register setting due to other loop regulations, such as dynamic power management (DPM) regulation (input voltage, input current) or thermal regulation. **If the input current or the input voltage reach their limits during the CV charge, the charge full termination is not influenced when the charge current is not so close to the EOC current specification.**

A new charge cycle starts when the following conditions are valid:

- The input power is recycled
- Battery charging is enabled by the I<sup>2</sup>C
- Auto-recharge kicks in

Under the following conditions:

- No thermistor fault at NTC
- No safety timer fault
- No battery over-voltage
- BATFET is not forced to turn off

### Automatic Recharge

When the battery is fully charged and the charging is terminated, the battery may be discharged due to system consumption or self-discharge. When the battery voltage is discharged below the recharge threshold, and V<sub>IN</sub> is still in the operation range, the IC begins another new charging cycle automatically without the requirement of restarting a charging cycle manually.

The auto-recharge function is valid only when EN\_BF = 1 and TERM\_TMR = 0.

### Battery Over-Voltage Protection (OVP)

The IC is designed with a built-in battery over-voltage limit about 130mV higher than V<sub>BATT\_REG</sub>. When the battery over-voltage event occurs, the IC suspends the charging immediately and asserts a fault.

### Input Current and Input Voltage Based Power Management

To meet the input source (usually USB) maximum current limit specification, the IC uses

input current-based power management by monitoring the input current continuously. The total input current limit can be programmed via the I<sup>2</sup>C to prevent the input source from overloading.

If the pre-set input current limit is higher than the rating of the input source, back-up input voltage-based power management also works to prevent the input source from being overloaded. If either the input current limit or the input voltage limit is reached, the Q1 MOSFET between IN and SYS are regulated so that the total input power is limited. As a result, the system voltage drops. Once the system declines to the minimum value of 4.56V or V<sub>IN</sub> - 160mV, the charge current is reduced to prevent the system voltage from dropping further.

Voltage-based DPM regulates the input voltage to V<sub>IN\_REG</sub> when the load is over the input power capacity. V<sub>IN\_REG</sub> set via the I<sup>2</sup>C should be at least 400mV higher than V<sub>BATT\_REG</sub> to ensure the stable operation of the regulator.

### Battery Supplement Mode

The charge current is reduced to keep the input current or input voltage in regulation when DPM occurs. If the charge current is at zero, and the input source is still overloaded due to a heavy system load, the system voltage starts to fall off. Once the system voltage falls below the battery voltage, the IC enters battery supplement mode. When the system voltage is 30mV below the battery voltage, the ideal diode mode is enabled. The battery MOSFET is regulated to maintain V<sub>BATT</sub> - V<sub>SYS</sub> at 22.5mV. If the supplement current I<sub>DSG</sub> \* R<sub>ON\_BATT</sub> is higher than 22.5mV, the battery MOSFET is fully turned on to keep the ideal forward voltage. When the system load decreases, once V<sub>SYS</sub> is higher than V<sub>BATT</sub> + 20mV, ideal diode mode is disabled.

Figure 4 shows the dynamic power management and battery supplement mode operation profile.

When V<sub>IN</sub> is not available, the IC operates in discharge mode, and the battery MOSFET is always fully on to reduce loss.

**Figure 4: Dynamic Power Management and Battery Supplement Operation Profile**

### Battery Charge Full Voltage

The battery voltage for the constant voltage regulation phase is  $V_{BATT\_REG}$ . When  $V_{BATT\_REG}$  is 4.2V, it has a  $\pm 0.5\%$  accuracy over the ambient temperature range of  $0^{\circ}\text{C}$  to  $+50^{\circ}\text{C}$ . When the battery is removed, the BATT voltage is between  $V_{BATT\_REG} - V_{RECHG}$  and  $V_{BATT\_REG}$ .

### Thermal Regulation and Thermal Shutdown

The IC monitors the internal junction temperature continuously to maximize power delivery and prevent the chip from overheating. When the internal junction temperature reaches the pre-set limit of  $T_{REG}$  (default  $120^{\circ}\text{C}$ ), the IC reduces the charge current to prevent higher power dissipation. The multiple thermal regulation thresholds from  $60^{\circ}\text{C}$  to  $120^{\circ}\text{C}$  help the system design meet the thermal requirement in different applications. The junction temperature regulation threshold can be set via Reg06 bit [1:0].

When the junction temperature reaches  $150^{\circ}\text{C}$ , both Q1 and Q2 are turned off.

### Negative Temperature Coefficient (NTC) Temperature Sensor

NTC allows the IC to sense the battery temperature using the thermistor usually available in the battery pack to ensure a safe

operating environment for the chip. A resistor with an appropriate value should be connected from VDD to NTC, and the thermistor should be connected from NTC to ground. The voltage on NTC is determined by the resistor divider, whose divide ratio depends on the temperature. The IC sets a pre-determined upper and lower bound of the divide ratio internally for NTC cold and NTC hot. In the MP2661, the I<sup>2</sup>C default setting is the PCB OTP. The function can be changed through the I<sup>2</sup>C (see Table 2).

**Table 2: NTC Function Selection Table**

I <sup>2</sup> C Control		Function
EN_NTC	ENB_PCB OTP	
0	x	Disable
1	1	NTC
1	0	PCB OTP

When PCB OTP is selected, if the NTC voltage is lower than the NTC hot threshold, both the LDO MOSFET and battery MOSFET are off. The PCB OTP fault sets the NTC\_FAULT status (Reg08 bit [1]) to 1 to indicate the fault. Operation resumes once the NTC voltage is higher than the NTC hot threshold.

The NTC function only works in charge mode. Once the NTC voltage falls out of the divide ratio (the temperature is outside the safe operating range), the IC stops the charging and reports it on the status bits. Charging resumes automatically after the temperature falls back into the safe range.

### Safety Timer

The IC provides both a pre-charge and fast-charge safety timer to prevent extended charging cycles due to abnormal battery conditions. The safety timer is one hour when the battery voltage is below  $V_{BATT\_LOW}$ . The fast charge safety timer begins when the battery enters fast charging. The fast charge safety timer can be programmed through the I<sup>2</sup>C. The safety timer feature can be disabled via the I<sup>2</sup>C.

The following actions restart the safety timer:

- A new charge cycle is kicked in
- Reg05 bit [7] is written from 0 to 1 (charge enable)
- Reg05 bit [3] is written from 0 to 1 (safety timer enable)
- Reg01 bit [7] is written from 0 to 1 (software reset)

### Host Mode and Default Mode

The IC is a host-controlled device. After the power-on reset, the IC starts in the watchdog timer expiration state or default mode. All registers are in the default settings.

Any write to the IC changes it to host mode. All charge parameters are programmable. If the watchdog timer (Reg05 bit [5:4]) is not disabled, the host must reset the watchdog timer regularly by writing 1 to the Reg01 bit [6] before the watchdog timer expires to keep the device in host mode. Once the watchdog timer expires, the IC returns to default mode. The watchdog timer limit can also be programmed or disabled by the host control. When there is no  $V_{IN}$ , the watchdog timer is suspended.

The operation can also be changed to default mode when one of the following conditions occur:

- Refresh input without battery
- Re-insert battery with no  $V_{IN}$
- Register reset Reg01 bit [7] is reset

### Battery Discharge Function

If battery is connected and the input source is missing, the battery MOSFET is fully on when  $V_{BATT}$  is above the  $V_{UV\_BATT}$  threshold. The 100mΩ battery MOSFET minimizes conduction loss during discharge. The quiescent current of the IC is as low as 11μA in this mode. The low on resistance and low quiescent current help extend the running time of the battery.

### Over-Discharge Current Protection

The IC has an over-discharge current protection in discharge mode and supplement mode. Once  $I_{BATT}$  exceeds the programmable discharge current limit (default 1.785A), the battery MOSFET is turned off after a 60μs delay, and the MP2661 enters hiccup mode in over-current

protection. The discharge current can be programmed high to 3.2A through the I<sup>2</sup>C. If the discharge current goes high to reach the internal fixed current limit (about 3.7A), the battery MOSFET is turned off and starts hiccup mode immediately.

Similarly, when the battery voltage falls below the programmable  $V_{UV\_BATT}$  threshold (default 2.8V), the battery MOSFET is turned off to prevent over-discharge.

### System Short-Circuit Protection (SCP)

The MP2661 features SYS node short-circuit protection (SCP) for the IN to SYS path and the BATT to SYS path.

The system voltage is continuously monitored. If  $V_{SYS}$  is lower than 1.5V, the system (SCP) for the IN to SYS path and the BATT to SYS path are active.  $I_{BATTOC}$  is decreased to half of the original value.

- 1) *IN to SYS path:* Once  $I_{IN}$  is over the protection threshold, both the LDO MOSFET and the BATT MOSFET are turned off immediately, and the IC enters hiccup mode. Otherwise, the max current limit and the setting input current limit are not reached, and  $I_{IN}$  is regulated at  $I_{INLMT}$ . Hiccup mode also starts after a 60μs delay. The interval of the hiccup mode is 800μs.
- 2) *BATT to SYS path:* Once  $I_{BATT}$  is over the 3.7A protection threshold, both the LDO MOSFET and the BATT MOSFET are turned off immediately, and the IC enters hiccup mode. When the battery discharge current limit threshold is reached, hiccup mode starts after a 60μs delay. The interval of the hiccup mode is 800μs.

If a system short-circuit occurs when both the input and battery are present, the protection mechanism of both paths work, with the faster one dominating the hiccup operation.

### Interrupt to Host (INT)

The IC has an alert mechanism which can output an interrupt signal via INT to notify the system of the operation by outputting a 256μs low-state INT pulse. All of the below events can trigger the INT output:

- Good input source detected
- UVLO or input OVP charge completed
- Charging status change
- Any fault in Reg08 (watchdog timer fault, input fault, thermal fault, safety timer fault, battery OVP fault, NTC fault)

When any fault occurs, the IC sends out an INT pulse and latches the fault state in Reg08. After the IC exits the fault state, the fault bit could be released to 0 after the host reads Reg08. The NTC fault is not latched and always reports the current thermistor conditions.

### Battery Disconnection Function

In applications where the battery is not removable, it is essential to disconnect the battery from the system for shipping mode. The MP2661 provides both shipping mode and system reset mode for different applications.

The IC has a register bit (FET\_DIS) for battery disconnection control. If this bit is set to 1, the MP2661 enters shipping mode, the battery MOSFET turns off, and the FET\_DIS bit refreshes to 0 after the battery MOSFET turns off. Pulling INT down for a very short time (>4s) wakes the MP2661 up from shipping mode.

The IC can also use INT to cut off the path from the battery to the system under the condition needed to reset the system manually. Once the logic at INT is set to low for more than 16s, the battery is disconnected from the system by turning off the battery MOSFET. The off state lasts for 4s, the battery MOSFET is turned on automatically, and the system is powered by the battery again. During the 4s off period, INT is not limited high or low. The IC can reset the system by controlling INT (see Figure 5).

## APPLICATION INFORMATION

### Selecting a Resistor for the NTC Sensor

NTC uses a resistor divider from the input source (VDD) to sense the battery temperature. The two resistors ( $R_{T1}$  and  $R_{T2}$ ) allow the high temperature limit and low temperature limit to be programmed independently. In other words, the IC can fit most types of NTC resistors and different temperature operation range requirements with the two extra resistors.  $R_{T1}$  and  $R_{T2}$  depend on the type of the NTC resistor and can be calculated with Equation (1) and Equation (2):

$$R_{T2} = \frac{(V_{COLD} - V_{HOT}) \times R_{NTCH} \times R_{NTCL}}{(V_{HOT} - V_{COLD}) \times R_{NTCL} - (V_{COLD} - V_{HOT}) \times R_{NTCH}} \quad (1)$$

$$R_{T1} = \frac{1 - V_{COLD}}{V_{COLD}} \times (R_{T2} // R_{NTCL}) \quad (2)$$

Where  $R_{NTCH}$  is the value of the NTC resistor at a high temperature of the required temperature operation range, and  $R_{NTCL}$  is the value of the NTC resistor at a low temperature.

### Selecting the External Capacitor

Like most low-dropout regulators, the MP2661 requires external capacitors for regulator stability and voltage spike immunity. The device is specifically designed for portable applications requiring minimum board space and small components. These capacitors must be correctly selected for optimal performance.

An input capacitor is required for stability. A capacitor at least 1 $\mu$ F must be connected between IN and GND for stable operation over the entire load current range. There can be more output capacitance than input as long as the input is at least 1 $\mu$ F.

The IC is designed specifically to work with a very small ceramic output capacitor (typically 2.2 $\mu$ F). A ceramic capacitor with X5R or X7R type dielectrics at least 2.2 $\mu$ F is suitable in the MP2661 application circuit. For the MP2661, the output capacitor should be connected between SYS and GND with thick traces and a small loop area.

A capacitor from BATT to GND is also necessary for the MP2661, and the typical capacitance value is 2.2 $\mu$ F. A ceramic capacitor with X5R or X7R type dielectrics at least 2.2 $\mu$ F is suitable for the application circuit.

A capacitor between VDD and GND is used to stabilize the VDD voltage to power the internal control and logic circuit. The typical value of this capacitor is 100nF.

### PCB Layout Guidelines

Efficient PCB layout is critical for stable operation. For best results, follow the guidelines below.

1. Place the external capacitors as close to the IC as possible to ensure the smallest input inductance and ground impedance.
2. Place the PCB trace connecting the capacitor between VDD and GND very close to the IC.
3. Keep the AGND for the I<sup>2</sup>C wire clean and away from PGND.
4. Place the I<sup>2</sup>C wire in parallel.
